Blueprint Thinking

What is HTML? How does the web work?

CHEAT SHEET

HTML

HyperText Markup Language. The code language that builds the structure of every webpage.

CSS

Colors, fonts, spacing, layout. CSS styles HTML. Nothing in CSS works without HTML first.

JavaScript

Clicks, animations, live data. JS makes pages respond. It needs HTML elements to target.

Browser

Chrome, Safari, Firefox. Reads your HTML top to bottom and turns it into a visible page.

Element

A single HTML component: heading, image, paragraph, button. Every visible thing is an element.

Tag

Marks where an element starts and ends. <h1> opens it. </h1> closes it.

<head>

Invisible section. Holds page title and browser setup info that visitors never see.

<body>

Everything visitors see and interact with on screen lives inside <body>.

THE HTML SKELETON

```
HTML
<!DOCTYPE html>    -- Tells the browser: this is HTML
<html>             -- Root element. Everything lives inside.
  <head>            -- Invisible setup section
    <title>My Page</title> -- Tab title in the browser
  </head>
  <body>            -- Everything visitors see goes here
    <h1>Hello!</h1>    -- Main heading
    <p>I built this.</p> -- Paragraph
  </body>
</html>            -- Close the root
```

RULES TO REMEMBER

- > Every opening tag needs a closing tag (except self-closing ones like).
- > The browser reads HTML top to bottom, in order. Sequence matters.
- > HTML describes WHAT things are. CSS describes how they LOOK.
- > One <h1> per page. Use h2 through h6 for sub-sections in order.
